

Helicopter Aerodynamics and Design Course Developed from a Research-Informed Framework

Ms. Antonette T. Cummings P.E., Purdue University

Antonette T. Cummings is a PhD candidate in Engineering Education at Purdue University. She earned her Bachelors and Masters in Mechanical Engineering at the University of Texas at Austin. She functioned as an aerodynamicist for military and civilian tiltrotors at Bell Helicopter for seven years, earning airplane and helicopter private pilot ratings. She has a Professional Engineer license in Texas in Thermal/Fluid Systems.

Dr. William "Bill" C. Oakes, Purdue University, West Lafayette

William (Bill) Oakes is the Director of the EPICS Program and one of the founding faculty members of the School of Engineering Education at Purdue University. He has held courtesy appointments in Mechanical, Environmental and Ecological Engineering as well as Curriculum and Instruction in the College of Education. He is a registered professional engineer and on the NSPE board for Professional Engineers in Higher Education. He has been active in ASEE serving in the FPD, CIP and ERM. He is the past chair of the IN/IL section. He is a fellow of the Teaching Academy and listed in the Book of Great Teachers at Purdue University. He was the first engineering faculty member to receive the national Campus Compact Thomas Ehrlich Faculty Award for Service-Learning. He was a co-recipient of the National Academy of Engineering's Bernard Gordon Prize for Innovation in Engineering and Technology Education and the recipient of the National Society of Professional Engineers' Educational Excellence Award and the ASEE Chester Carlson Award. He is a fellow of the American Society for Engineering Education and the National Society of Professional Engineers.

Helicopter Aerodynamics and Design Course Developed from a Research-Informed Framework

I. Introduction

This document describes an introductory helicopter aerodynamics and design engineering course for undergraduates in aeronautical or aerospace engineering. The three major sections of this document are Content, Assessment, and Pedagogy. These sections have been developed according to Engineering Education research principles and findings, such that the three sections are aligned with one another. Each section presents at least one tool to guide course development. The course’s foundation is to provide authentic practice for meaningful learning. The primary purposes of this paper are to present a unified strategy and a toolkit for developing engineering courses in Figure 1 and to use helicopter aerodynamics as an applied example.

Figure 1. Strategy and toolkit for Backwards Design of courses.

The course content emphasizes understanding of pilot controls of the hardware of a rotor, mathematical modeling of theoretical performance models, and design of a rotor to meet a defined mission. The assessment strategies are based on the types of learning in this course, where project-based learning and design thinking employ higher levels of thinking and therefore need the matched assessment strategy of a rubric. Pedagogy is primarily based on Perkins’ *Making Learning Whole*, where certain elements for the student are emphasized: distributed, deliberate practice; intrinsic motivation and choice; working on the hard parts with feedback and assessment; participation in a community of practice; and metacognition.

The content and assessment strategies of this course are intended to emphasize a student’s ability to think like an aerodynamicist, a design engineer and a helicopter pilot; especially where the answers are not known beforehand, the engineer must show a logical process in finding at least one acceptable solution. The pedagogy is driven by research results and recommendations from several disciplines. The day-to-day course activities are developed “downstream” of the content, the assessment strategies, and the pedagogy, instead of simply following the chapter order of a respected textbook.

The content reflects the commonly held understandings that multiple leading universities document in their course descriptions. The assessment strategies reflect the varied results that students may generate with higher level thinking. The pedagogy reflects the established trend of cooperative learning as the “best” form of active, student-centered learning, where the instructor scaffolds the student’s learning process and develops the student’s ability to pursue self-guided inquiry, which is the highest goal of teaching.

It is expected that the institutional setting will be an ABET-accredited engineering college that offers aerospace engineering at the bachelors level. For example, the rotorcraft centers of excellence are Georgia Tech, University of Maryland, and Penn State ^[1]. Kansas University offers a professional short course for helicopters. Purdue University and Arizona State have offered a helicopter course as recently as 2012. These institutions have developed plans of study to support a complex subject such as helicopter aerodynamics.

It is expected to offer the course to undergraduates who have fulfilled key mechanical and aerospace prerequisites. The prerequisites include: introduction to kinematics, machine elements, introduction to dynamic systems and controls, introduction to fluid mechanics, and introduction to aerodynamics. These prerequisites have their own prerequisites, such as physics, calculus, and mechanics of solids. These subjects will have introduced the concepts: rotational axis system; aerodynamic forces and moments in the translational axis system; time-dependency of forces and moments; and functions of common helicopter parts. These prerequisites are necessary for design. It is likely because of so many prerequisites that this course will be junior or senior level.

II. Content

The content of this course is arranged according to the principles of Backward Design ^[2]. The concepts are arranged according to Enduring Understandings, items that are Important-to-Know, and items that are Good-to-be-Familiar-With. Enduring Understandings are defined as the big ideas that are retained after many details have been forgotten ^[2], items that students remember five years later. The next section describes the concepts that fit into these three categories. In the Concept Map section below, the process of converging upon these categories for these concepts is described. Existing helicopter course descriptions from other prominent universities are shown for comparison to this proposed content and assessment.

Three universities are considered helicopter centers of excellence: Georgia Institute of Technology, Pennsylvania State University, and University of Maryland College Park. An online search of these schools’ websites yielded course descriptions, syllabi, and required texts of helicopter courses. Penn State offers undergraduate and graduate level courses, including a first year introduction. Georgia Tech and Arizona State provide senior level courses; Georgia Tech offers two semesters of specialization. The University of Maryland, Purdue University, and Kansas University only provide masters level courses.

Georgia Tech’s course AE4358 has five course objectives: “Identify and explain the purpose of key elements of a rotorcraft configuration; Utilize actuator disk theory to analyze rotor system performance; Utilize rotor blade element theory to analyze rotor system performance; Predict

rotorcraft performance such as maximum speed, maximum rate of climb, endurance, etc; Use the Rf design process to size a rotorcraft configuration against a given mission”^[3]. These five course objectives are very similar to the Enduring Understandings and the learning objectives listed in the next sections.

Arizona State offers a Rotary Wing Aerodynamics and Performance class, which is described as “Introduces helicopter and propeller analysis techniques. Momentum and blade-element, helicopter trim. Hover and forward flight. Ground effect, autorotation and compressibility effects”^[4]. The required textbook is *Principles of Helicopter Aerodynamics* by Gordon Leishman of the University of Maryland. The content listed here is similar to Georgia Tech’s content. The textbook from another center of excellence demonstrates a close-knit community of practice^[5], with the particular competence of helicopter aerodynamics and design.

A. Enduring Understandings

Helicopters are unique because of the rotor at the top that does most of the work, second to that of the pilot. How the pilot interacts with the helicopter is of paramount importance in design. The rotor is typically made of many moving parts, the largest and most noticeable of which are the blades, the hub, and the swashplate, all of which operate in rotation as a function of time. The pilot commands the forces generated by the rotor through the controls in order to accomplish a mission, whether it be hover, forward flight, or some combination of both. Therefore, Enduring Understanding 1 is: The student will be able to describe the rotor and blade motions in a rotational reference axis system and the student will be able to identify rotor designs and the allowable controls between the pilot and the rotor. This is shown best in Figure 3 and Figure 4 for the pilot controls to the main rotor.

A rotor designer is different from a pilot in that a designer can make a prediction of rotor performance, given a particular shape or configuration, whereas a pilot plans a mission around known performance capabilities. (Performance has multiple definitions in helicopters; performance of the rotor considers thrust generated and power required; performance of the total aircraft considers maximum attainable altitude, speed, gross weight, and range on a tank of fuel.) There are four common theoretical models of increasing fidelity to the physical geometry of the rotor, and therefore increasing mathematical complexity. The student will be able to construct mathematical representations of different theoretical models that predict rotor lift, drag, thrust, and power required. Therefore, Enduring Understanding 2 is: The student will be able to calculate performance using theoretical mathematical models of a rotor, and list the assumptions and limitations of each of the theoretical models. This is shown best in Figure 5.

A rotor designer is also different from a pilot in that a designer can design an optimum configuration to satisfy a given mission. The engineering student should practice substantiating and defending all their claims and decisions with sound engineering data. Therefore, Enduring Understanding 3 is: The student will draw upon a broad knowledge base of mission maneuvers, performance prediction tools, and rotor designs to create and select an optimum configuration to meet or exceed a defined mission. This is shown best in Figure 5.

Expressing the differences between design engineers and pilots highlights the fact that engineers think in a particular way and behave accordingly. One mode of behavior among engineers is to

distribute cognition among specialists ^[6], which necessitates particular vocabulary for efficient communication. Another aspect of engineering thinking is to test large prototypes by first applying calculations where possible and by devising a rigorous test through careful planning. Therefore, Enduring Understanding 4 is: To develop design engineering thinking and technical communication. This Understanding is really an Outcome, is more difficult to measure, and is beyond the scope of this course for assessing. These will be practiced, however, in the various assignments of the course.

B. Important-to-Know

Important-to-Know is defined as the knowledge and skills that the student should master by the conclusion of the course, or prerequisite knowledge and skills in order to accomplish key performances ^[2]. Overlapping micro-concepts that are Important-to-Know are shown in blue in Figure 2. There are six clusters of micro-concepts, starting from bottom left of Figure 2 and moving clockwise.

- Lift distribution from four effects on the rotor in forward flight.
- Motions of the blade from three possible hinges. Motions are a result of aerodynamic forces.
- Hub configurations based on which motions are allowed and constrained by the hinges at the hub. Because the blades are subject to large aerodynamic forces, the blades themselves may still flap (out-of-plane), feather (twist in-plane), or experience lead-lag (translation in-plane).
- Angular effects of RPM, rotor coning, and the Coriolis effect.
- Four controls available to the pilot. Collective and cyclic (longitudinal and lateral) control the main rotor. Anti-torque pedals control the tail rotor (a conventional tail rotor can be designed just as the main rotor at the top of the helicopter is designed; if the student knows the main rotor, the instructor assumes that the student can design the tail rotor. Other tail configurations are beyond the scope of this course).
- Four common mathematical models of the rotor. It is possible to combine the momentum theory and blade element theory models. There also exists vortex theory. Since industry is moving towards computational fluid dynamics (CFD), this is important to know for new graduates.

There are macro-concepts built from the above micro-concepts. These are shown in Figure 2 in blue, closer to the purple Enduring Understandings. Descriptions below start from the center left of the Figure.

- Forward flight. One of the main interests in this class is the performance of the rotor in forward flight. However, for total mission performance, the student must know lift, drag, and pitching moment of the fuselage, which knowledge may have been gained in a prerequisite course.
- Hover, which is the main virtue of helicopters and merits the most study. When a rotor is attached to a fuselage, the fuselage may experience pendular action, which is of interest to a pilot for the purpose of controlling it.

- The rotor wake, as a consequence of the blade shape. The wake structure will change as a function of aircraft velocity. The wake can also be affected by its proximity to the ground (ground effect).
- Rotor blades, which will be the primary focus of optimizing performance for a mission.
- Hub, which has historical and manufacturer-specific significance. Understanding this invites a student into the helicopter community of practice.
- Mission, which is the deciding element of sizing a rotor and fuselage. Analyzing a mission for its most demanding segments will have been explored in a prerequisite course, at least for fixed wing solutions. There will be some exploration in this course about analyzing a mission for hover segments.
- Flight Test. It is important to know that there is such a thing as flight test. Since no theoretical model is complete, the rotor designer should know that a logical next step after design is to build and to test the configuration. Planning flight test is a component of engineering thinking within Enduring Outcome 4. Planning for flight test includes identifying critical input parameters, critical output parameters, and permutations of the key inputs that produce a safe-to-risky ordering of test points. Flight test is listed as Important-to-Know because this course will not include practice for planning flight test points according to risk.

C. Good-to-Be-Familiar-With

Good-to-be-Familiar-With is defined as the field of possible content that might be examined during the course, but acknowledging that we cannot address all areas ^[2]. In Figure 3, shown in green are some items that a rotor designer would need to be familiar with from a design perspective. The overlapping circles indicate micro-concepts whereas the independent circles represent macro-concepts.

- Twist, chord, airfoils, planform, and tip shape are facets of the blade's aerodynamic shape. Chord and airfoils are concepts covered in prerequisite aerodynamics courses. Twist, planform, and tip shape are rotor-specific concepts.
- The swashplate is a unique helicopter part that links pilot control stick movement to rotor movement, manifested mostly in collective pitch of the blades and the tip path plane of the whole rotor. Its function is in Enduring Understanding 1; its form is good-to-be-familiar-with.
- The pilot has control of the entire aircraft, with control sticks in particular governing the rotor. The pilot also has training in mission planning, normal operations and maneuvers, and emergency operations and maneuvers.
- Downwash is the resulting deflected airflow as the blades generate a pressure difference. Its distribution is dependent upon the blade shape, the collective pitch of the blades (requiring power from the engine to maintain normal RPM), and the velocity of the entire aircraft.
- Tip vortex is a nontrivial contributor to overall rotor performance in hover because most of the useful work of the rotor occurs between 75% radius and the tip. The tip vortex shed by one rotor blade may impede the performance of the advancing blade behind it as the blades rotate about the hub.

Figure 3. Detailed concept map for rotor, blades, hub, and controls.

Figure 4. Detailed concept map of rotor with Good-to-be-Familiar-With Conservation of Angular Momentum and Control Loads.

over lectures and textbooks in problem-based learning in order to teach difficult engineering concepts.

Other researchers, in proving the usefulness of simulations for teaching, highlighted typical problems that students encounter. In broad categories, students have difficulty with generating hypotheses, with designing experiments, with interpreting data, and with planning and self-monitoring^[10]. Related researchers identify these problems not as concepts, but as learning processes^[11]. Because these difficult skills are included in the Enduring Understandings of this course, it is important to provide repeated practice and feedback to the students to master these skills.

III. Assessment

This section presents several tools that help align assessment strategies with course content as presented in the previous section. Firstly, the Content of the Section II is mapped to Bloom's Taxonomy. Secondly, assessment strategies are developed for the Enduring Understandings of this course through Assessment Triangles and Assessment Worksheets. Thirdly, a rubric is shown in Appendix C for the most comprehensive Enduring Understanding, shown as an authentic task.

A. Learning Objectives for the Entire Course

The revised Bloom's Taxonomy recommends the construction of learning objectives with one noun (as a direct object) and one verb as a cognitive process^[12]. The concepts in Figure 2 are used as the nouns; therefore, highlighted in the list below are only Enduring Understandings and Important-to-Know items. These concepts are validated by comparing to the objectives as written by Georgia Tech.

1. The student shall recall the motions of a blade and of a rotor.
2. The student shall describe the rotational reference axis system of a rotor.
3. The student shall identify the controls of a rotor blade.
4. The student shall describe the wake structure of a rotor.
5. The student shall contrast in-ground effect to the out-of-ground effect on the wake.
6. The student shall model or draw the balance of forces of a rotor in hover.
7. The student shall subdivide the effects of forward flight on a rotor.
8. The student shall construct a model of performance for the rotor, using Momentum Theory, Blade Element Theory, or Vortex Theory.
9. The student shall compare and contrast the performance models.
10. The student shall calculate total mission performance of a rotor in hover and in forward flight.
11. The student shall select an optimum configuration of a helicopter for a given mission.
12. The student shall plan for flight test of total performance of a helicopter.
13. The student shall measure performance of a helicopter in a flight test.

B. Tool - Mapping the Learning Objectives to Bloom's Taxonomy

The front cover of the revised Bloom's Taxonomy provides a table in which to map the learning objectives of a course so as to assist in crafting appropriate teaching and assessment strategies. The numbers in Section III.A and the abbreviations EU, IMP, and FAM to represent Enduring Understanding, Important-to-Know, and Good-to-be-Familiar-With concepts are used as identifiers in this section. Table 2 below shows the concepts mapped into the revised Bloom's Taxonomy. Four Enduring Understandings as from the concept map are listed, while the remaining Important-to-Know items are summarized versions of the items in the concept map.

Table 2. Learning Objectives mapped to the revised Bloom's Taxonomy.

	Remember	Understand	Apply	Analyze	Evaluate	Create
Factual						
Conceptual	1 – IMP	2 – IMP 6 – IMP	<u>3 – EU</u> 4 – IMP	5 – IMP 7 – IMP 9 – IMP		
Procedural				<u>10 – EU</u>	<u>11 – EU</u>	<u>8 – EU</u> 12 – IMP 13 – IMP
Metacognitive						

C. Tool - Assessment Triangles

For this assignment, assessment triangles are developed for the three most important Learning Objectives, identified in Table 2 as 3, 8, and 11 Enduring Understandings. Cognition, Observation, and Interpretation corners constitute the assessment triangle^[13], where the Cognition corner should be developed first. For all the Learning Objectives, the cognitive perspective as described by Pellegrino is adopted, where students actively construct knowledge by trying to connect new information to prior knowledge. The preferred method of cognition is the strong method, which is to learn a domain-specific algorithm. Since this course should be at the junior or senior level, the students will be encouraged to connect new helicopter information to previously-gained engineering knowledge.

To answer the question about how students will learn the Enduring Understandings of this course, this course will employ equal parts mental simulation, project-based learning, and design thinking, with some expectation of rote memorization. These learning activities will be shown in the assessment triangles below.

1. Enduring Understanding 1 – Learning Objectives 1, 2, 3, 4

The student will be able to describe the rotor and blade motions in a rotational reference axis system and the student will be able to identify rotor designs and the allowable controls between the pilot and the rotor.

Cognition Corner – Mechanical reasoning by mental simulation will require a student to construct a mental model of a dynamic system; the student will probably follow the system piecewise^[14]. The student can develop a mental model by articulating inputs and reactions of a

dynamic system with many moving parts. Rote memorization plays a small role in this course because of unique names given to helicopter-specific parts, such as a blade, a hub, and a swashplate. Supporting memorization requires prior experiences ^[15], which implies exposure and repetition.

Observation Corner – The student will be provided an exploded view and an assembly view of an existing helicopter rotor system without any parts labeled. In the images, the student will label the components of the rotor, such as the rotor shaft, the hub, the swashplate, the flap hinge, the lead-lag hinge, and the pitch link. Alternatively, the student may be provided or may construct a physical model of a rotor system out of simple prototyping materials, Legos, or K'nex type materials.

The student may choose to draw motions of a rotor blade, where the blade is rigid in the chordwise direction and that the slender beam can have bending and rotating motions (this is an application of engineering beam theory). The student will identify out-of-plane motion of the blade from the flap hinge. The student will identify in-plane motion of the blade from the lead-lag hinge. The student will identify feathering motion from the pitch links.

The student may choose to draw swashplate pictures showing a tilt change from neutral position, or an elevation from neutral position, as indicators of cyclic inputs or collective pitch inputs. The student may draw before-after pictures of blade coning, blade flapping, and blade feathering. The student may draw pictures of lift distribution and Mach number distribution across the span of the rotor blade in hover. The student may write equations for the conservation of momentum, with the Coriolis Effect and rotor speed or RPM.

Alternatively, the student may choose to use a physical model of an articulated rotor with a swashplate to describe verbally and demonstrate physically inputs and reactions. The student may move parts statically to describe the resulting blade motion. The student will identify lateral cyclic and longitudinal cyclic inputs from the swashplate. The student may spin the rotor and move parts to describe the resulting blade motion. Alternatively, the student may move the pilot control sticks and verbally describe the resulting motions in the rotor system.

Interpretation Corner – Complete descriptions of the components and the possible motions are available in chapter seven of the classic textbook by Gessow ^[16] and in chapter five of the helicopter text by Stepniewski and Keys ^[17]. The instructor will compare the student's labels and drawings to the textbook illustrations. With the alternative observation of the student manipulating a physical model, the instructor will compare the student's movement of rotor parts, coupled with verbal descriptions, to the textbook illustrations.

2. Enduring Understanding 2 – Learning Objectives 8 and 9

The student will be able to calculate performance using theoretical mathematical models of a rotor, and list the assumptions and limitations of each of the theoretical models.

Cognition Corner – Project-based learning takes place in an authentic task ^[18]; an authentic task may be a student building his or her own math model, based on a helicopter theory, to compare with textbook equations and results. The student will develop the project by applying computer

programming skills to create a compiled code or create a spreadsheet with equations central to the theory being modeled. The student will make conjectures on the impact of included and excluded physical phenomena for each of the theories.

Observation Corner – There are four commonly-used domain-specific algorithms for modeling the performance of a helicopter rotor, listed here in increasing complexity (and therefore, accuracy and computational time required): momentum theory, blade element theory, vortex theory, and CFD. (CFD modeling of helicopters is still being developed in peer-reviewed research journals, with some frameworks available^[19] and will therefore not be emphasized, but at least mentioned.) The student will create a spreadsheet or compiled program for each of the first three listed math models, identifying key inputs and key outputs available in the different models.

The student will calibrate or validate his or her spreadsheets or codes of the three models by using parameters of an existing helicopter and its accompanying performance as documented in the flight manual. The student will create plots of blade performance for key input and output parameters as a function of blade span, or total rotor performance as the model allows. The student will create plots of thrust versus power required for hover and forward flight.

Interpretation Corner – Complete descriptions of the first three theories are available in chapters 2, 3, and 4 of Stepniewski's book. The instructor will compare codes or spreadsheets input to the textbook equations for the three models. The instructor will compare outputs to his own constructed math models. The instructor could compare outputs of the math models to performance charts of existing products, with the caveat that the models are incomplete such that the analytical and flight-test-measured results will not match within 3% accuracy.

3. Enduring Understanding 3 – Learning Objectives 10 and 11

The student will draw upon a broad knowledge base of mission maneuvers, performance prediction tools, and rotor designs to create and select an optimum configuration to meet or exceed a defined mission.

Cognition Corner – Design thinking can be learned by doing, by iterating and receiving feedback, and by dialoguing with artifacts and other people^[20], as in working in a team, with a professor, to design a helicopter to meet a particular mission. The designer predicts range, maximum speed, payload, fuel required and cost of a rotor configuration. The designer then compared results to mission specifications and iterates until mission specifications are met. The designer must also compare results to the limits of reasonable design, such as disk loading, advance ratio, drag and compressibility as a function of Mach number, solidity, airfoil stall, and control loads. The novice designer should take care not to exceed these limits. The student should compare his or her calculations to those presented in class.

Observation Corner – There does not appear to be a concise method for optimizing a helicopter rotor because each parameter is a tradeoff to another; rather, there exists an energy balance method for analyzing the mission for power required, fuel, and payload. Staying within the above-mentioned limits allows a designer to select tip speed, twist, planform, number of blades,

and airfoil sections. A mission will be defined by the instructor. The student will complete the following steps:

- translate the mission legs into helicopter rotor parameters (defined in the cognition corner)
- determine the most demanding mission segments as the design point
- outline reasonable limits for each of the rotor parameters
- identify trade-offs between rotor parameters
- select airfoil, tip speed, rotor radius, chord, twist, number of blades, and number of rotors
- calculate hover and forward flight performance of the given selection
- iterate until a solution is found to meet the mission; plots will be created

Interpretation Corner – Suggestions and hints to optimization of a rotor design can be found in the previously mentioned texts, such as all of second half of Stepniewski's book and chapter seven of Johnson's book ^[21]. The instructor will check the work for the above seven steps. The instructor will confirm that the design stayed within reasonable limits. The instructor will check plots created, if any, for validity and comprehensiveness. The instructor will check that the final proposed configuration and performance predictions at least appear to meet the mission.

D. Tool - Assessment Worksheets

Assessment worksheets are shown for the top three learning objectives for which there are assessment triangles. The assessment worksheet shows the claim, the task, and the evidence for the learning objective ^[22].

1. Enduring Understanding 1 – Learning Objectives 1, 2, 3, 4

The student will be able to describe the rotor and blade motions in a rotational reference axis system and the student will be able to identify rotor designs and the allowable controls between the pilot and the rotor.

General – The student will be provided an exploded view and an assembly view of an existing helicopter rotor system without any parts labeled. The student will be instructed to label hardware of a rotor. The student will be instructed to draw and label allowable motions of the rotor blade. The student will be instructed to describe pilot input controls and resulting rotor motions.

Claim – The student will be able to draw and name aerodynamic and inertial forces and moments of a rotor in a rotational axis system. The student will be able to draw and name blade motions in a rotational axis system. The student will be able to show cause and effect of control inputs on individual rotor blade motions.

Task – The student will label images and diagrams of the hardware of a rotor. The student will draw vectors of forces and moments on the rotor blades and assign the proper names of the forces, moments, and motions. The student will make a model of a rotor with a spinning disk on a mast to narrate gyroscopic motion.

Evidence – The student will have written labels on images of hardware of a rotor. The student will label flapping, feathering, and lead-lag motions with vectors and arrows. The student will label lift, centrifugal force, drag, and pitching moment with vectors and arrows. The student will show that a force input on a spinning disk has its full effect 90 degrees later. The student will describe pilot control inputs' effects on rotor motions.

2. Enduring Understanding 2 – Learning Objectives 8 and 9

The student will be able to calculate performance using theoretical mathematical models of a rotor, and list the assumptions and limitations of each of the theoretical models.

General – The student will be instructed to build his own mathematical models in a spreadsheet or compiled code of his choice. The student will be instructed to show results of the models compared to existing helicopters.

Claim – The student will identify key assumptions for each mathematical model for rotor and blade performance. The student will identify sources of information required for each model. The student will build a mathematical model of each model.

Task – The student will list assumptions for each model, expressed mathematically where possible. The student will identify key output parameters when using the models. The student will draw pictures of the unit of calculation for each theory (momentum theory analyzes a disk, regardless of blades; blade element theory analyzes a blade within a rotor; vortex theory analyzes the rotor wake). The student will show governing mathematical equations and operationalized calculations. The student will list possible output variables in each model. The student will input key parameters of an existing helicopter and plot the outputs of the three models to the performance data of the existing helicopter.

Evidence – The student will have a spreadsheet or code in electronic form. The student will have a list of inputs and outputs for each mathematical model. The student will have a list of governing equations for each model. The student will have a list of assumptions for each model. The student will have graphs of hover and forward flight performance data from each of the models and from an existing helicopter.

3. Enduring Understanding 3 – Learning Objectives 10 and 11

The student will draw upon a broad knowledge base of mission maneuvers, performance prediction tools, and rotor designs to create and select an optimum configuration to meet or exceed a defined mission.

General – The student will be instructed to make an argument that a particular configuration of a helicopter meets the given mission. The student will substantiate the argument with data generated from the mission description and from at least one mathematical model from Enduring Understanding 2.

Claim – The student will be able to calculate hover and forward flight performance, predict mission range from performance calculations, and match to a defined mission.

Task – The student will itemize key mission specifications. The student will model hover and forward flight performance using theoretical mathematical models of a rotor. The student will calculate mission fuel required and mission range achieved.

Evidence – The student will create a table or a mission diagram. The student will create and use a spreadsheet or a compiled code of the mathematical model. The student will create graphs of mathematical model inputs and outputs as compared to mission thresholds.

E. Authentic Tasks

Hansen outlines six characteristics of authentic tasks in which students will gain an understanding and an appreciation for the subject ^[23]. It appears that the Enduring Understanding 3 of designing a helicopter to meet a mission has five of the six characteristics. The characteristics are:

- realistically contextualized
- require judgment and innovation
- ask student to “do” the subject
- replicate key challenging situations in which professionals are truly “tested” in their field
- assess student’s ability to use a repertoire of knowledge and skill
- allow opportunities to rehearse, practice, and get feedback

A typical military contractor may answer a Request For Proposal ^[24]. The RFP will define a mission or series of missions that the vehicle is expected to complete and will define any other constraints or requirements, such as the use of parts already in inventory or compliance with other existing systems such as GPS. The contractors are typically given 90 to 120 days to make a proposal and submit a bid. The proposal process is the context of the rotor design process, where the engineers analyze the missions, size the vehicle, review their historical data for cost, weight and performance, and propose development time and testing time required. Emulating this RFP process emphasizes five of the six authentic task characteristics.

The sixth characteristic of providing opportunity for practice and feedback shall be incorporated into the course for the benefit of the students. The details of this are provided in the week-by-week Lesson Plan in Appendix B.

F. Tool - Rubric

Hansen proposes that a rubric to assess a student’s performance of a task should contain three aspects: dimensions of quality, level of mastery attained, and commentary ^[23]. The dimensions of quality should be criteria from theories of critical thinking and be specific to the discipline. The levels of mastery should have a label for which a point value can be attached, and the number of levels should be dependent on the complexity of the task. The commentary should indicate a student’s strengths and weaknesses on the performance of the task. The rubric in general should be provided to students beforehand in order for them to practice self-assessment. The rubric also communicates key criteria of the discipline to students.

For this course, a rubric for one Enduring Understanding 3, the most comprehensive and most authentic one in this course, is developed. This Enduring Understanding is computationally intense, so the rubric centers on careful mathematical modeling. Appendix C shows the rubric for three levels of mastery on four dimensions of quality.

IV. Pedagogy

A. Cognitive Theory of Learning

Svinicki summarizes the best theories for learning, with cognitive theory described by Piaget at the top^[25]. Firstly in cognitive theory, a learner receives new information by paying attention to it with his senses. Secondly, the information moves to working memory or short-term memory and is compared to existing memory. Thirdly, if the information is found to be meaningful in working memory, it moves to long-term memory by being encoded in a network of organized associations. Svinicki also describes concept learning theory as long term memory being made of “schemata all interconnected in an organized manner”. Svinicki then describes constructivist theory as a learner having schemata that are “a very complex and unique world view peculiar to each individual, having been constructed out of all the learner’s prior experiences”. These theories, if incorporated into teaching and learning, have the implication that the student must have deliberate and distributed practice with the content in order to learn. Learning here means encoding information into long-term memory.

B. Work on the Hard Parts

This section outlines the printed material that will be provided to the student at the beginning of the course. The foundation of this part of the course is the inclusion of the seven principles of *Making Learning Whole*^[8] in order to outline to the student *how* and *why* the content will be taught in this course. Perkins’ principles, from an extended sports analogy, are explained with some details in the list and in Table 3 below:

- Play the whole game – To find a problem; To get better at something; Deliberate rehearsal; reflection.
- Make the game worth playing – Intrinsic motivation; Give students a choice; Make the most of the student’s imagination.
- Work on the hard parts – Identify troublesome knowledge; Deliberate practice of deconstructing and reconstructing difficult part so that they are executed in new and better ways; Ongoing assessment and feedback from instructor.
- Play out of town – Transfer of knowledge; Learning by doing.
- Uncover the hidden game – Learning strategies, causal thinking, systems phenomena; Uncover tacit messages that people send by their conduct.
- Learn from the team – Peer problem solving; Community of practice; Mentors.
- Learn the game of learning – Cognitive apprenticeship; Reflection.

Table 3. Perkins' *Making Learning Whole* principles incorporated into this course.

Principle	Example in this course	Details
Play the whole game	Designing a rotor in response to a Request for Proposal; Incorporating previously acquired engineering knowledge about forces, moments, kinematics, machine elements, airfoils, and mission modeling	Section III.E Section III.D.3
Make the game worth playing	A generative topic with disciplinary and societal significance	Section III.E
Work on the hard parts	Deconstruction of theoretical mathematical models of rotor performance in order to reconstruct for the purpose of optimization and design of a new rotor	Section II.E
Play out of town	Going back and forth between theory and examples; Calibration and comparison of theoretical mathematical models to the measured performance of an existing helicopter product; Make broad generalizations of the theoretical models through reflective thinking	Table 4, Table 5, Table 6, Table 7 helpful resources columns
Uncover the hidden game	Students have difficulty with generating hypotheses, designing experiments, and planning	Section II.E
Learn from the team	Enduring Understandings 1, 2 and 3 shall be team efforts because of the broad and detailed scope of each; there shall be resource interdependence in-class; students shall rotate through 4 teams during the course	Table 4, Table 5, Table 6, Table 7 in-class activity columns
Learn the game of learning	Iterating efficiently in design (using elements in Uncover the hidden game) and shall be scaffolded by the instructor with in-class tasks, accompanying worksheets ^[9] , rubrics provided beforehand, and coaching by the instructor	Table 4, Table 5, Table 6, Table 7 assignments due columns; Section III.F

C. Tool - Syllabus and Lesson Plan

The syllabus is in Appendix A. Figure 6 in the syllabus was developed from Fink's^[26] template of lesson plans for structuring the sequence of content in a course. The first step is to list the learning goals from Section III.A into Fink's Worksheet 1 for designing a course, and to address 1) ways of assessing this kind of learning 2) actual teaching-learning activities and 3) helpful resources for each learning goal. The results of Worksheet 1 in Table 4, Table 5, Table 6, and Table 7 are shown in Appendix B. Secondly, the learning goals should be introduced, as in Figure 6 below, such that the subsequent topic includes the previous topic. Arrows between topics show inclusion of previous topics into new topics from left to right. As noted in the Content Section II of this paper, it is possible that the course time limitations may hinder

completion of Learning Objectives 12 and 13 of planning flight test, but it is better to plan for more content in a course than less, in case the students demonstrate heightened aptitude and interest in the subject.

Figure 6. Sequence of content for 15 week helicopter aerodynamics course.

A high quality lesson plan contains the following elements: General Objectives; Specific Objectives; List of Activities and Timeline; Concepts in The Lesson; Outline of How Concepts Will Be Taught; Description of Learning Activity; How Learning Will Be Assessed. In Appendix B, grouped according to Enduring Understandings and Important-to-Know items, the lesson plan is shown for this 15 week course with the above elements itemized. To be consistent in Table 4, Table 5, Table 6, and Table 7 truncated descriptions are used in Figure 6, which are built from the list in Section III.A. Much larger descriptions of the ways of assessing are described in Assessment Section III above.

D. Other Elements in Development

Certain elements in the lesson plan tables bear further discussion and substantiation because these elements must be prepared by the instructor because they are not simply chapters out of a textbook. Firstly, the audio-tutorial method is detailed in *Teaching Engineering* chapter 8^[27] where lectures and accompanying printed materials are provided to the student outside of class; this is also referred to as the flipped classroom^[28]. This method is enhanced here in this course by video lecture to include demonstration of moving parts. Additionally, the instructor must prepare a number of different worksheets to guide student’s inquiry for the content: rotor hardware, rotor motions, rotor controls, rotor forces and moments in hover, rotor forces and moments in forward flight, experiments with a wind tunnel simulation tool, and a flight test plan. This document does not develop any of these items specifically.

Certain elements in the lesson plan need to be located for the students before class. Firstly, the instructor needs to find a wind tunnel or a wind tunnel simulation in order for the students to examine a rotor wake. It might be best if the simulation tool were based upon Computational Fluid Dynamics, as this theoretical model is more likely to capture more physical phenomena than the three models explored in this course. The nature of CFD software is such that one can query macro-level and micro-level elements, such as a summed force on a rotor blade or a certain location around a rotor blade. Secondly, the instructor needs to provide performance charts from existing helicopter flight manuals for the students to read and use for comparisons to their theoretical mathematical models. Fast and inexpensive CFD wind tunnel model for helicopter rotors are necessary but difficult to find. Performance charts are readily available in flight manuals that all helicopter pilots must have; the flight manuals also provide descriptions of the rotor, such that key parameters can be extracted and applied to the theoretical mathematical models for calibration.

V. Conclusions and Recommendations

This document presents major steps to guide the development of a course: Backward Design for identifying and categorizing key concepts; identifying attributes of difficult concepts; identifying the foundational theory of learning; aligning concepts to Bloom's Taxonomy; aligning assessment of concepts through assessment triangles and assessment worksheets; arranging assessment around authentic tasks in the field; developing a rubric for an authentic task; aligning weekly lessons to practice the difficult concepts; and aligning the weekly lessons to a logical build-up of concepts. These nine steps may be time-consuming for the course developer (the instructor) but ensure an active and interactive learning experience that is deliberate, distributed practice to master difficult engineering concepts.

The strategies shown here are not new within the last decade, but each of are grounded in research and theory of learning. Quite a few of the tools may seem familiar to seasoned instructors. The strategies and tools are also aligned here as a more complete toolkit for novice teachers of engineering to have alignment of knowledge and activities in engineering science and design courses. As professional engineers practice design using toolkits, so educators can practice design of courses using a toolkit. The author is awaiting the opportunity to teach this course, with a critical eye on methodically assessing this toolkit's effectiveness.

Many great researchers inwardly confess that they are not taught to teach. This example shows that a well-designed course does not rely solely on an instructor's dynamic and engaging personality. Rather, it relies on an instructor's deep knowledge of the subject, theoretically and practically, and on a logical uncovering of the key concepts. Following these principles for course design will strengthen a professor's portfolio of research, publishing, teaching, and service.

Appendix A - Syllabus

Course Goals, Objectives, and Expectations

This course is designed to introduce undergraduate aeronautical engineering students to helicopter rotor aerodynamics, with an emphasis on theoretical mathematical modeling of rotor performance for designing a rotor to meet a defined mission composed of hover and forward flight.

By the end of the course, the student should be able to:

- name and describe helicopter rotor hardware
- understand the helicopter pilot perspective of control of the rotor
- understand aerodynamic forces and moments in the rotor
- describe three theoretical mathematical models for rotor performance, including their assumptions and limitations
- apply these mathematical models to the design of a new rotor for a given mission
- engage in general engineering design practices, such as design notebooks and reflection
- be conversant with engineers who know other aspects of helicopter design, such as handling qualities, loads and fatigue, and propulsion

Criteria for Grading and Grading Standards

The student shall be graded on the quality of the worksheets and reports generated for each assignment. Upper-class undergraduates are expected to use engineering vocabulary and knowledge from prerequisite courses and this course in order to write professional technical reports. Teamwork is an element of each assignment and the student shall also be graded on participation and distribution of workload in the team as reported by their teammates.

The reports shall be clear and detailed on project definition, assumptions, data sources, operationalization of theoretical models, and results of those models. The recommendations of the reports shall be clearly stated and shall be numerically precise.

Specific Criteria for Each Graded Assignment

Each graded assignment will have a rubric. The student shall be provided the rubric before the assignment is due so that the student may check his own work before submitting for a grade. Certain assignments will have closed-form numerical solutions as criteria in the rubric, such as the building of a mathematical model for comparison to an existing helicopter product. Certain assignments will have open-ended responses, such as the design of a new rotor to meet a new mission.

Description of Class, Including Description of and Rationale for Teaching Method

The three credit hour course shall meet once a week in a three hour session with the instructor. This class will follow the flipped classroom model, where text reading and lecture will occur before class on a student's own time and class meeting time will be spent on working through examples and class assignments in small teams. Additionally, the in-class sessions will include multiple laboratory-like opportunities for visualization of and experimentation with aerodynamic phenomena, where worksheets will be provided to guide students' own inquiry. In class, the

students will have access to physical models of helicopter rotors for hands-on exploration and discovery.

How Students Prepare for and Behave During Class Session

The flipped classroom model employs pre-recorded lectures for students to listen to or view before class on their own time. The instructor shall make these videos and accompanying slides (visual content) available to the students a week before each in-class session. The student is expected to take notes in a design notebook so that the student may refer to and employ the content during in-class sessions. Reflection notes along with lecture notes are highly encouraged so that the student reminds himself to ask the instructor about confusing content in the next in-class session.

During the in-class sessions, the student is expected to bring his own design notebook. The student may also bring his own computer as the course moves to mathematical modeling and design. The student will participate actively in worked examples and team assignments and will contribute equal labor to the team assignments. DO NOT simply copy others' work or notes and expect that you will understand it.

What Students Can Expect from Instructor

The instructor shall be prompt in providing a schedule of activities and relevant material at least one week in advance. The instructor shall provide rubrics as assignments are given and shall abide by the standards in the rubrics for grade determination. The instructor shall provide feedback on draft reports one week before reports are due. The instructor shall return graded assignments one week after student submission.

The instructor shall make frequent use of the student's prior knowledge of fixed wing aerodynamics. The instructor shall coach students in self-guided inquiry. The instructor shall model engineering and design thinking as was practiced in private industry. The instructor shall model helicopter pilot thinking. The instructor shall provide weekly office hours (TBD) for consultation for the assignments or for anything else that might be on the student's mind.

Advice on How to Read/Approach Materials

Helicopters are a complex culmination of multiple disciplines of engineering, so materials attempting to explain helicopters thoroughly will be short and complicated, or very long and simplified. Also, engineers and pilots together still do not know everything about how helicopters really work, so there will be unanswered questions and unexplained phenomena. Do the work so that you will develop a "gut feeling"; this will prepare you to answer the unanswered questions when you enter the workforce.

The student should be prepared to commit significant time (possibly years) understanding how all the hardware moves and how all the air flows. Some of what you already know from previous fixed wing classes will be applicable to this course. Skip to the pictures in the textbooks, but be clear that pictures do not convey rotating parts and aerodynamic phenomena very well. Do watch the lecture videos for moving parts and airflow visualization.

Take advantage of powerful computing capacity because there will be many parameters and variables to consider. Refresh yourself on programming (C, MatLab or other familiar code) or using spreadsheets (Excel) because of the intense focus on calculations in this course. Make notes in your code or spreadsheet to remind yourself of the names, uses and units of the different variables. Maintain a naming convention for your files and your experiments because there will likely be many files building upon each other.

Schedule of Material Each Time Students Meet
(see Figure 6)

Appendix B – Lesson Plan

Table 4. Lesson plan for Enduring Understanding 1.

Week	Learning Goal	Ways of Assessing	Teaching-Learning Activities	Helpful Resources	Out-of-Class Activity Before	In-Class Activity	Assignment due
1	Rotational reference axis system	Comparing labeled images to textbook;	Lecture with sketches;	Textbooks;	Obtain bound notebook	Intro to class, individual pre-test for prior knowledge	Labeled worksheets
2	Motions of blades and rotors	Comparing labeled images to textbook	Review 2-d schematics of many rotors; constructing and manipulating 3-D models	Prototype materials; scale model or remote control helicopter	Video lecture with demos	Prototyping models with Team1	Labeled worksheets
3	Controls of blades and rotors	Comparing verbal descriptions of inputs and rotor responses to textbook	Review 2-d schematics of many rotors; constructing and manipulating 3-D models	Heli-chair ^[29] and remote control model helicopter	Video lecture with real flight manual images	Build and fly Heli-chair and RC model with Team1	Labeled worksheets

Table 5. Lesson plan for Important-to-Know forces in hover, forward flight; wake structure.

Week	Learning Goal	Ways of Assessing	Teaching-Learning Activities	Helpful Resources	Out-of-Class Activity Before	In-Class Activity	Assignment due
4	Forces and moments in hover	Comparing labeled images to textbook	Lecture with sketches; rapid experiments	Textbooks; wind tunnel simulation tool	Video lecture with worked examples of calculations	Simulations, with worksheets to guide experiments with Team2	Labeled worksheets of images, completed experiment worksheets
5	Forces and moments in hover	Comparing labeled images to textbook	Lecture with sketches; rapid experiments	Textbooks; wind tunnel simulation tool	Video lecture with worked examples of calculations	Simulations, with worksheets to guide experiments with Team2	Labeled worksheets of images, completed experiment worksheets
6	Forces and moments in forward flight	Comparing labeled images to textbook	Lecture with sketches; rapid experiments	Textbooks; wind tunnel simulation tool	Video lecture with worked examples of calculations	Simulations, with worksheets to guide experiments with Team2	Labeled worksheets of images, completed experiment worksheets

7	Forces and moments in forward flight	Comparing labeled images to textbook	Lecture with sketches; rapid experiments	Textbooks; wind tunnel simulation tool	Video lecture with worked examples of calculations	Simulations, with worksheets to guide experiments with Team2	Labeled worksheets of images, completed experiment worksheets
8	Wake structure	Comparing labeled images to textbook	Flow visualization experiments	Textbooks; lab equipment: pressure gauges, smoke, scale model of rotor	Video lecture with real flight test videos, wind tunnel videos	Physical experiment, with worksheets to guide experiments with Team2	Lab report with pictures, test points, input parameter sweeps, outputs measured
